

Note of Fast Runner

Ken

June, 2018*

1 About systems and methods

1.1 Requirements - system

- List of assumptions
- Capture the required parameters (i.e. how to normalize the systems)
 - Resonance
 - Nonlinear elastic components
 - * a set of linear components for multiple modes?
-

1.2 Requirements - method

- Applicable to complex system (e.g. for the designed mechanism)
- Nondimensionlization (so that it can be used for robots with different scales)
- Stability analysis
- Robustness

1.3 Remarks

- Impact does not cause velocity change on runner with massless leg!
- In SCS, to simulate massless leg, it is better to use only one body, and manipulate the relation between the contact point and the body in controller instead.

1.4 ToDo

- Rearrange/updating references for fastRunner
- Check if the foot is sliding
- Check optimization tools ihmcc have
 - parameter optimization tool using Gradient Decent or GA
- Ask Cris about the parameter range/selection

*Last update: July 24, 2018

1.5 Questions

Direction

- Should I exclude the gyroscopic-based stabilization?
- Eigen values of linearized system, Poincare map analysis, anything else I should study for the stability analysis?
- The linkage between the control in simulation and mechanism design
 - Parameters
 - How to design a mechanism can emulate PD control?

General Utilities

- Any solver for nonlinear program IHMC used?
- Any trajectory optimization package IHMC used?
- Methods to get stable Reciprocating Spoked Runner?

Past simulations

- Why the abstract runner (in spoked runner project) can be stabilized in x direction?

Figure 1: The Abstract Runner

- The simulation setup is really robust for a large set of initial conditions/throttle angles
- It turns out its because the added wind resistance dissipate a lot of energies.
- Methods to get stable Reciprocating Spoked Runner?
- What is the line private static final long serialVersionUID for?

2 Pitch Stability of an Vertically Open-loop Hopper

2.1 Jorge Cham's Dissertation - openloop control of 1DOF vertical hopper

Figure 3-1. The vertical hopping model used for analysis. The hopper's leg consists of a spring, a damper and a force element which is active according to a binary motor pattern. The figure shows a sample trajectory of the hopper, the different modes that it goes through, and the events that trigger the transitions between the modes.

Figure 2: The schematic of a 1 DOF hopper [11]

2.1.1 Equation of motion

Using the model as shown in Fig. 2, during the stand phase (i.e. $y \leq 0$), the equation of motion can be expressed as:

$$m\ddot{y} = -b\dot{y} - ky - mg + f$$

where m is the mass, b is the damping, k is the stiffness, f is the control input. Normalized by weight, the equation becomes

$$\ddot{y} = -b/m\dot{y} - k/my - g + f/m$$

Expressed in state space form:

$$\begin{bmatrix} \dot{y} \\ \ddot{y} \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ -k/m & -b/m \end{bmatrix} \begin{bmatrix} y \\ \dot{y} \end{bmatrix} + \begin{bmatrix} 0 \\ -g + f/m \end{bmatrix} \quad (1)$$

or equivalently

$$\dot{X} = \begin{bmatrix} 0 & 1 \\ -\omega^2 & -2\xi\omega \end{bmatrix} X + \begin{bmatrix} 0 \\ -g + f_n(t) \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ -k_p & -k_d \end{bmatrix} X + \begin{bmatrix} 0 \\ -g + f_n(t) \end{bmatrix} \quad (2)$$

where $X \triangleq [y, \dot{y}]^T$. When the hopper is in the air (i.e. $y > 0$, flight phase),

$$\dot{X} = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} X + \begin{bmatrix} 0 \\ -g \end{bmatrix} \quad (3)$$

Define the force of an open-loop motor pattern

$$f_n(t) = \begin{cases} f/m, & \text{if } t_{off} < t < t_{off} + t_{on}. \\ 0, & \text{otherwise.} \end{cases} \quad (4)$$

2.2 Stability Analysis of an Open-loop Controlled Hopper with Discrete Pitch Angle Control

Use the state space of z motion form 2 with a simplified open-loop force input:

$$\begin{bmatrix} \dot{z} \\ \ddot{z} \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ -kp_z & -kd_z \end{bmatrix} \begin{bmatrix} z \\ \dot{z} \end{bmatrix} + \begin{bmatrix} 0 \\ -g + f_n(t) \end{bmatrix} \quad (5)$$

where

$$f_n(t) = \begin{cases} f_n \triangleq f/m, & \text{if } t_{flight} < t < t_{flight} + t_{contact}. \\ 0, & \text{otherwise.} \end{cases} \quad (6)$$

To further simplify the problem, assuming $f_n(t)$ is much more dominant than $-kp_z z - kd_z \dot{z} - g$ so that:

$$\begin{bmatrix} \dot{z} \\ \ddot{z} \end{bmatrix} \approx \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} z \\ \dot{z} \end{bmatrix} + \begin{bmatrix} 0 \\ f_n(t) \end{bmatrix} \quad (7)$$

Assumptions:

- $f_n(t)$ ¹ can induce stable vertical hopping motion.
- t_0 starts when the foot leaves the ground.
- $t_{flight} + t_{contact} = T$, $t_{contact} = \alpha$, and $T > \alpha$

Then the pitch dynamics with feedback control can be expressed as:

$$\begin{bmatrix} \dot{\theta} \\ \ddot{\theta} \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} \theta \\ \dot{\theta} \end{bmatrix} + \begin{bmatrix} 0 \\ -f_n(t)m/I\Delta x \end{bmatrix} \quad (8)$$

2.2.1 Poincare Section

Denote the state at the n^{th} step Poincare section $\theta_n, \dot{\theta}_n$ (defined at the start of the flight phase). Then we can calculate the state at Poincare section at the $n+1^{th}$ step:

$$\dot{\theta}_{n+1} = \dot{\theta}_n - \frac{f}{I} \Delta x t_{contact} \quad (9)$$

$$\theta_{n_{touchDown}} = \theta_n + \dot{\theta}_n t_{flight}$$

$$\dot{\theta}_{n_{touchDown}} = \dot{\theta}_n$$

$$\begin{aligned} \theta_{n+1} &= \theta_n + \dot{\theta}_n t_{flight} + \dot{\theta}_n t_{contact} - \frac{1}{2} \frac{f}{I} \Delta x t_{contact}^2 \\ &= \theta_n + T \dot{\theta}_n - \frac{1}{2} \frac{f}{I} \alpha^2 \Delta x \end{aligned} \quad (10)$$

2.2.2 Poincare Map of Pitch Dynamics with Proportional Control

By designing a proportional control such that $\Delta x = k\phi_n$ and defining $K = \frac{1}{2} \frac{f}{I} k$, Eq. 9 and Eq.10 can be expressed as follows:

$$\begin{aligned} \theta_{n+1} &= \theta_n - \alpha^2 K \theta_n + T \dot{\theta}_n \\ \dot{\theta}_{n+1} &= \dot{\theta}_n - 2\alpha K \theta_n \end{aligned}$$

¹Conceptually, the $f_n(t)$ can be treated as a force applied from a nonlinear component which connects the massless leg to the body (so there is no velocity change happen at foot strike)

Arranged them in the state space equation, we can get a discrete map M (i.e. Poincare Map, with set of difference equations):

$$\begin{bmatrix} \theta_{n+1} \\ \dot{\theta}_{n+1} \end{bmatrix} = \begin{bmatrix} 1 - \alpha^2 K & T \\ -2\alpha K & 1 \end{bmatrix} \begin{bmatrix} \theta_n \\ \dot{\theta}_n \end{bmatrix} = M \begin{bmatrix} \theta_n \\ \dot{\theta}_n \end{bmatrix} \quad (11)$$

Eigen value analysis

To analyze the stability of the equation in 11, we need to check whether the eigen values of Poincare map M are within the unit cycle. Similar to the Routh-Herwitz method for the continuous map, we can use Jury Stability Test (Ogata, 1985)², which states that a discrete system of two dimensions with the characteristic equations $P(z)$ of the form:

$$P(z) = a_0 z^2 + a_1 z + a_2$$

where $a_0 > 0$, is stable if the following conditions are all satisfied:

$$\begin{aligned} |a_2| &< a_0 \\ a_0 + a_1 + a_2 &> 0 \\ a_0 - a_1 + a_2 &> 0 \\ |(a_0 + a_2)(a_2 - a_0)| &> |a_1(a_0 - a_1)| \end{aligned}$$

For a Jacobian of the form

$$J = \begin{bmatrix} J_1 & J_2 \\ J_3 & J_4 \end{bmatrix}$$

The characteristics equation can be expressed as follows:

$$P(z) = z^2 - (J_1 + J_4)z + (J_1 J_4 - J_2 J_3)$$

Substituting into the stable conditions stated above,

$$|(J_1 J_4 - J_2 J_3)| < 1 \quad (12)$$

$$1 - (J_1 + J_4) + (J_1 J_4 - J_2 J_3) > 0 \quad (13)$$

$$1 + (J_1 + J_4) + (J_1 J_4 - J_2 J_3) > 0 \quad (14)$$

$$|(1 + (J_1 J_4 - J_2 J_3))((J_1 J_4 - J_2 J_3) - 1)| > |(J_1 + J_4)(1 + (J_1 + J_4))| \quad (15)$$

Check condition Eq.12:

First assuming $1 - \alpha^2 K + 2T\alpha K > 0$

$$\begin{aligned} 1 - \alpha^2 K + 2T\alpha K &< 1 \\ \rightarrow -\alpha^2 K + 2T\alpha K &< 0 \\ \rightarrow \alpha K(-\alpha + 2T) &< 0 \end{aligned}$$

Since $\alpha > 0$, $K > 0$, and $T > \alpha$, the assumption cannot satisfy the condition.

Next, assuming $1 - \alpha^2 K + 2T\alpha K < 0$:

$$\begin{aligned} 1 - \alpha^2 K + 2T\alpha K &> -1 \\ \rightarrow -1 + \alpha^2 K - 2T\alpha K &< 1 \\ \rightarrow \alpha K(\alpha - 2T) &< 2 \end{aligned}$$

²contents quoted from [11]

Since $T > \alpha$, the condition can always be satisfied, as long as the following condition is satisfied:

$$(J_1 J_4 - J_2 J_3) = (1 - \alpha^2 K + 2T\alpha K) < 0$$

Combine conditions above we can get a new inequality as follows:

$$-1 < (J_1 J_4 - J_2 J_3) = (1 - \alpha^2 K + 2T\alpha K) < 0 \quad (16)$$

Check condition Eq.13:

$$\begin{aligned} 1 - (1 - \alpha^2 K + 1) + (1 - \alpha^2 K + 2T\alpha K) &> 0 \\ &\rightarrow 2T\alpha K > 0 \end{aligned}$$

From the last inequality we can get the condition is always hold.

Check condition Eq.14:

$$\begin{aligned} 1 + (1 - \alpha^2 K + 1) + (1 - \alpha^2 K + 2T\alpha K) &> 0 \\ &\rightarrow 4 - 2\alpha^2 K + 2T\alpha K > 0 \\ &\rightarrow 4 + \alpha K(-2\alpha + 2T) > 0 \end{aligned}$$

From the last inequality we can get the condition is always hold.

Check condition Eq.15:

Based on Eq. 16, the left hand side of Eq. 15 can be rearranged as :

$$|(det(M) + 1)(det(M) - 1)| = |det(M)^2 - 1| = 1 - det(M)^2$$

From Eq. 13 and 14 we can got $(J_1 + J_4) > 0$, therefore the right hand side of Eq. 15 can be rearranged as:

$$|(J_1 + J_4)(J_1 + J_4 + 1)| = (J_1 + J_4)(J_1 + J_4 + 1)$$

Therefore the Eq. 15 can be expressed as follows:

$$1 - det(M)^2 > tr(M)(tr(M) + 1)$$

where $det(M) = \prod_i \lambda_i = (J_1 J_4 - J_2 J_3)$ is the determinant of matrix M and $tr(M) = \sum_i \lambda_i = (J_1 + J_4)$ is the trace of the matrix M .

To sum up

For the (Poincare) stability, the following conditions need to be satisfied:

$$-1 < det(M) < 0 \quad (17)$$

$$0 < tr(M)(tr(M) + 1) < 1 - det(M)^2 \quad (18)$$

where

$$\begin{aligned} det(M) &= 1 - \alpha^2 K + 2T\alpha K \\ tr(M) &= 2 - \alpha^2 K \\ K &= \frac{1}{2} \frac{f_n}{I} k \end{aligned}$$

Result

After check the sign of the $det(M)$, it was found that $det(M)$ always > 0 :

$$1 - \alpha^2 K + 2T\alpha K = 1 + \alpha K(-\alpha + 2T) > 0$$

Therefore, it is concluded that proportional control with this system setup cannot stabilize the pitch dynamics.

2.2.3 Poincare Map of Pitch Dynamics with PD Control

By designing a PD control such that $\Delta x = k_p \theta_n + k_d \dot{\theta}_n$ and defining $K = \frac{1}{2} \frac{f}{I} k_p$, $C = \frac{1}{2} \frac{f}{I} k_d$, Eq. 9 and Eq.10 can be expressed as follows:

$$\begin{aligned}\theta_{n+1} &= \theta_n - \alpha^2 K \theta_n + T \dot{\theta}_n - \alpha^2 C \dot{\theta}_n \\ \dot{\theta}_{n+1} &= \dot{\theta}_n - 2\alpha K \theta_n - 2\alpha C \dot{\theta}_n\end{aligned}$$

Arranged them in the state space equation, we can get a discrete map M_{pd} :

$$\begin{bmatrix} \theta_{n+1} \\ \dot{\theta}_{n+1} \end{bmatrix} = \begin{bmatrix} 1 - \alpha^2 K & T - \alpha^2 C \\ -2\alpha K & 1 - 2\alpha C \end{bmatrix} \begin{bmatrix} \theta_n \\ \dot{\theta}_n \end{bmatrix} = M_{pd} \begin{bmatrix} \theta_n \\ \dot{\theta}_n \end{bmatrix} \quad (19)$$

2.2.4 Analytical Solution for Eq.7

Start from t_0 (the beginning of the flight phase), assuming $Z = [0, \dot{z}_0]^T$, then we can get:

$$z(t_{flight}) = \dot{z}_0 t_{flight} - 1/2 g t_{flight}^2 = 0 \quad (20)$$

$$\dot{z}(t_{flight}) = \dot{z}_0 - g t_{flight} = -\dot{z}_0 \quad (21)$$

where a constraint for the \dot{z}_0 can be derived:

$$\dot{z}_0 = 1/2 g t_{flight} \quad (22)$$

$$(23)$$

Then we can derive the solution at the end of the touch down:

$$z(1) = -\dot{z}_0 t_{contact} + (f/m - g) t_{contact}^2 = 0 \quad (24)$$

$$\dot{z}(1) = -\dot{z}_0 + (f/m - g) t_{contact} = \dot{z}_0 \quad (25)$$

where another constraint for the \dot{z}_0 can be derived:

$$\dot{z}_0 = 1/2 (f/m - g) t_{contact} \quad (26)$$

Period T , contact force f and $t_{contact}$ are dependent From Eqs. 26 and 22 we can get

$$\begin{aligned} 1/2 g t_{flight} &= 1/2 (f/m - g) t_{contact} \\ \rightarrow t_{flight} &= (f/mg - 1) t_{contact} \\ \rightarrow t_{flight} + t_{contact} &= T = (f/mg) t_{contact} \end{aligned}$$

2.3 Stability Analysis of an Open-loop Controlled Hopper with Continuous Pitch Angle Control

Consider the case that $\Delta x = k\theta(t)$ or $\Delta x = k_p\theta(t) + k_d\dot{\theta}(t)$, then the pitch angle will be controlled continuously in the stance phase.

2.3.1 Poincare map of Hopper with Continuous Proportional Control

Assuming $\Delta x = k\theta(t)$, then the system dynamic in the stance phase becomes:

$$\dot{X} = \begin{bmatrix} \dot{\theta} \\ \ddot{\theta} \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ -k\frac{f}{I} & 0 \end{bmatrix} X \triangleq \begin{bmatrix} 0 & 1 \\ -2K & 0 \end{bmatrix} X = AX \quad (27)$$

where $K = \frac{1}{2}\frac{f}{I}k$. Again denoting the state at the n^{th} step Poincare section $X_n = [\theta_n, \dot{\theta}_n]^T$ (defined at the start of the flight phase). Then we can first calculate the touchdown state at n_{th} step:

$$\begin{aligned} \theta_{nTD} &= \theta_n + \dot{\theta}_n t_{flight} \\ \dot{\theta}_{nTD} &= \dot{\theta}_n \end{aligned}$$

and $X_{nTD} = [\theta_{nTD}, \dot{\theta}_{nTD}]^T$ then can be expressed as:

$$X_{nTD} = \begin{bmatrix} 1 & (T - \alpha) \\ 0 & 1 \end{bmatrix} X_n \quad (28)$$

Next, assuming the contact time is exactly $t_{contact} = \alpha$ (e.g. no perturbation in z direction), then the $X_{n+1} = [\theta_{n+1}, \dot{\theta}_{n+1}]^T$ can be expressed with $X_{nTD} = [\theta_{nTD}, \dot{\theta}_{nTD}]^T$:

$$X_{n+1} = e^{A\alpha}(X_{nTD} - X_{eq}) + X_{eq} \quad (29)$$

$$= e^{A\alpha} \left(\begin{bmatrix} 1 & (T - \alpha) \\ 0 & 1 \end{bmatrix} X_n - X_{eq} \right) + X_{eq} \quad (30)$$

where $X_{eq} = [0, 0]^T$ is the equilibrium point of Eq. 27. Therefore, we can get the Poincare map in this case is:

$$M = e^{A\alpha} \left(\begin{bmatrix} 1 & (T - \alpha) \\ 0 & 1 \end{bmatrix} \right) \quad (31)$$

Using symbolic tool in MATLAB, we can derive the closed-form expression of M as follows:

$$M = \begin{bmatrix} M_{11} & M_{12} \\ M_{21} & M_{22} \end{bmatrix}$$

where

$$\begin{aligned} M_{11} &= \frac{e^{\sqrt{2}\sqrt{-K}a}}{2} + \frac{e^{-\sqrt{2}\sqrt{-K}a}}{2} \\ M_{12} &= \left(\frac{e^{\sqrt{2}\sqrt{-K}a}}{2} + \frac{e^{-\sqrt{2}\sqrt{-K}a}}{2} \right) (T - a) + \frac{\sqrt{2}e^{\sqrt{2}\sqrt{-K}a} - \sqrt{2}e^{-\sqrt{2}\sqrt{-K}a}}{4\sqrt{-K}} \\ M_{21} &= \frac{\sqrt{2}\sqrt{-K}e^{\sqrt{2}\sqrt{-K}a}}{2} - \frac{\sqrt{2}\sqrt{-K}e^{-\sqrt{2}\sqrt{-K}a}}{2} \\ M_{22} &= \frac{e^{\sqrt{2}\sqrt{-K}a}}{2} + \frac{e^{-\sqrt{2}\sqrt{-K}a}}{2} + \left(\frac{\sqrt{2}\sqrt{-K}e^{\sqrt{2}\sqrt{-K}a}}{2} - \frac{\sqrt{2}\sqrt{-K}e^{-\sqrt{2}\sqrt{-K}a}}{2} \right) (T - a) \end{aligned}$$

2.3.2 Poincare Map of Hopper with Continuous PD Control

Assuming $\Delta x = k_p \theta(t) + k_d \dot{\theta}(t)$, then the system dynamic in the stance phase becomes:

$$\dot{X} = \begin{bmatrix} \dot{\theta} \\ \ddot{\theta} \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ -k_p \frac{f}{I} & -k_d \frac{f}{I} \end{bmatrix} X \triangleq \begin{bmatrix} 0 & 1 \\ -2K & -2C \end{bmatrix} X = AX \quad (32)$$

$$M_{pd} = e^{A\alpha} \begin{bmatrix} 1 & (T - \alpha) \\ 0 & 1 \end{bmatrix} \quad (33)$$

Using symbolic tool in MATLAB, we can derive the closed-form expression of M_{pd} as follows:

$$M_{pd} = \begin{bmatrix} M_{11} & M_{12} \\ M_{21} & M_{22} \end{bmatrix}$$

where

$$\begin{aligned} M_{11} &= \frac{C e^{a\sqrt{C^2-2K}-Ca} - C e^{-Ca-a\sqrt{C^2-2K}} + e^{a\sqrt{C^2-2K}-Ca} \sqrt{C^2-2K} + e^{-Ca-a\sqrt{C^2-2K}} \sqrt{C^2-2K}}{2\sqrt{C^2-2K}} \\ M_{12} &= \frac{e^{a\sqrt{C^2-2K}-Ca} - e^{-Ca-a\sqrt{C^2-2K}}}{2\sqrt{C^2-2K}} + \\ &\quad \frac{(T-a) \left(C e^{a\sqrt{C^2-2K}-Ca} - C e^{-Ca-a\sqrt{C^2-2K}} + e^{a\sqrt{C^2-2K}-Ca} \sqrt{C^2-2K} + e^{-Ca-a\sqrt{C^2-2K}} \sqrt{C^2-2K} \right)}{2\sqrt{C^2-2K}} \\ M_{21} &= - \frac{K e^{a\sqrt{C^2-2K}-Ca} - K e^{-Ca-a\sqrt{C^2-2K}}}{\sqrt{C^2-2K}} \\ M_{22} &= \frac{C e^{-Ca-a\sqrt{C^2-2K}} - C e^{a\sqrt{C^2-2K}-Ca} + e^{a\sqrt{C^2-2K}-Ca} \sqrt{C^2-2K} + e^{-Ca-a\sqrt{C^2-2K}} \sqrt{C^2-2K}}{2\sqrt{C^2-2K}} - \\ &\quad \frac{(T-a) \left(K e^{a\sqrt{C^2-2K}-Ca} - K e^{-Ca-a\sqrt{C^2-2K}} \right)}{\sqrt{C^2-2K}} \end{aligned}$$

2.3.3 General Solution of Poincare Map of Hybrid Linear Systems

$$\dot{Z} = AZ + B \quad (34)$$

where **A is invertible**. If the **mode transistion is time-based**, then we can augment the state of the system with t :

$$\dot{X} = \begin{bmatrix} \dot{t} \\ \dot{Z} \end{bmatrix} = \begin{bmatrix} 0 & 0 \\ 0 & A \end{bmatrix} X + \begin{bmatrix} 1 \\ B \end{bmatrix} \quad (35)$$

where $X = [t, Z]^T$. Assuming the mode trasition happened under the following condition:

$$e^T X = 0 \quad (36)$$

and takes time Δt from X_n to X_{n+1} , then the Poincare map (Jacobian matrix) can be expressed as:

$$\frac{\partial X_{n+1}}{\partial X_n} = -\dot{X}_{n+1}(e^T \dot{X}_{n+1})^{-1}e^T \begin{bmatrix} 1 & 0 \\ 0 & e^{A\Delta t} \end{bmatrix} + \begin{bmatrix} 1 & 0 \\ 0 & e^{A\Delta t} \end{bmatrix} \quad (37)$$

3 2D Spoked Runner with Centered Mass

Extended from the vertical hopper, this model is aimed to use for analysis of coupled dynamics of the spoked runner, which has following assumptions

- massless leg
- COM at the center with a "locked" flywheel

3.1 System Kinematics

As indicated in Fig XXX, the position of the body (mass) is

$$\begin{aligned}x &= l \cos \theta \\z &= l \sin \theta\end{aligned}$$

and the velocity

$$\begin{aligned}\dot{x} &= \dot{l} \cos \theta - l \sin \theta \dot{\theta} \\ \dot{z} &= \dot{l} \sin \theta + l \cos \theta \dot{\theta}\end{aligned}$$

3.1.1 Lagrangian Mechanics

Wit the velocity of the mass, the Lagrangian L can be expressed as:

$$\begin{aligned}L = T - V &= \frac{1}{2}m(\dot{x}^2 + \dot{y}^2) + \frac{1}{2}I\dot{\theta}^2 - V_{spring} - V_{gravity} \\ &= \frac{1}{2}m(\dot{l}^2 + l^2\dot{\theta}^2) + \frac{1}{2}I\dot{\theta}^2 - \frac{1}{2}k(l - l_0)^2 - mg(l \sin \theta)\end{aligned}$$

where $I = mr_g^2$. Take l, θ as the generalized coordinate, the equation of motions are:

Stance Dynamics

$$\begin{aligned}m\ddot{l} - ml^2\dot{\theta}^2 + k(l - l_0) &= -mg \sin \theta \\ 2ml\dot{\theta} + m(l^2 + r_g^2)\ddot{\theta} &= -mgl \cos \theta\end{aligned}$$

Flight Dynamics

$$\begin{aligned}\ddot{y} &= -g \\ \ddot{\theta} &= 0 \\ \text{LO: } l &= l_0 \\ \text{TD: } y &= l_0 \sin \beta \\ \text{Spoked TD: } \theta &= \beta + \frac{2\pi}{d}\end{aligned}$$

where β is the touch down angle, d is the number of the legs the spoked runner has.

3.2 System Kinematics

As indicated in Fig XXX, the position and the velocity of the frame m are:

$$\begin{aligned}x &= l \cos \theta \\ z &= l \sin \theta \\ \dot{x} &= \dot{l} \cos \theta - l \sin \theta \dot{\theta} \\ \dot{z} &= \dot{l} \sin \theta + l \cos \theta \dot{\theta}\end{aligned}$$

The position and the velocity of the body m_b are:

$$\begin{aligned}x_b &= l \cos \theta + r_c \cos(\theta + \phi) \\z_b &= l \sin \theta + r_c \sin(\theta + \phi) \\\dot{x}_b &= \dot{l} \cos \theta - l \sin \theta \dot{\theta} - r_c \sin(\phi)(\dot{\phi}) \\\dot{z}_b &= \dot{l} \sin \theta + l \cos \theta \dot{\theta} + r_c \cos(\phi)(\dot{\phi})\end{aligned}$$

3.2.1 Lagrangian Mechanics

With the velocity of the masses, the Lagrangian L can be expressed as:

$$\begin{aligned}L = T - V &= \frac{1}{2}m(\dot{x}^2 + \dot{z}^2) + \frac{1}{2}m_b(\dot{x}_b^2 + \dot{z}_b^2) - V_{spring} - V_{gravity} - V_{b_{gravity}} \\&= \frac{1}{2}m(\dot{l}^2 + l^2\dot{\theta}^2) + \frac{1}{2}m_b(\dot{l}^2 + l^2\dot{\theta}^2 + r_c^2\dot{\phi}^2 - 2\dot{\phi}r_c\dot{l}\sin(\phi - \theta) - l\dot{\theta}r_c\cos(\phi - \theta)) - \\&\quad \frac{1}{2}k(l - l_0)^2 - mg(l\sin\theta) - m_bg(l\sin\theta + r_c\sin(\phi))\end{aligned}$$

EOM of l :

$$\begin{aligned}\frac{\partial L}{\partial l} &= -(m + m_b)g\sin\theta + (m + m_b)l\dot{\theta}^2 - k(l - l_0) \\\frac{\partial L}{\partial \dot{l}} &= (m + m_b)\dot{l} \\\frac{d}{dt}\frac{\partial L}{\partial \dot{l}} &= (m + m_b)\ddot{l}\end{aligned}$$

EOM of θ :

$$\begin{aligned}\frac{\partial L}{\partial \theta} &= -(m + m_b)gl\cos\theta - m_bg r_c \cos(\theta + \phi) \\\frac{\partial L}{\partial \dot{\theta}} &= (m + m_b)l^2\dot{\theta} + m_br_c^2(\dot{\theta} + \dot{\phi}) \\\frac{d}{dt}\frac{\partial L}{\partial \dot{\theta}} &= (m + m_b)l^2\ddot{\theta} + 2(m + m_b)l\dot{l}\dot{\theta} + m_br_c^2(\ddot{\theta} + \ddot{\phi})\end{aligned}$$

EOM of ϕ :

$$\begin{aligned}\frac{\partial L}{\partial \phi} &= -m_bg r_c \cos(\theta + \phi) \\\frac{\partial L}{\partial \dot{\phi}} &= m_br_c^2(\dot{\theta} + \dot{\phi}) \\\frac{d}{dt}\frac{\partial L}{\partial \dot{\phi}} &= m_br_c^2(\ddot{\theta} + \ddot{\phi})\end{aligned}$$

Take l , θ , ϕ as the generalized coordinate, the equation of motions are:

$$\begin{aligned}(m + m_b)\ddot{l} - (m + m_b)l^2\dot{\theta}^2 + k(l - l_0) &= -(m + m_b)g\sin\theta \\(m + m_b)l^2\ddot{\theta} + 2(m + m_b)l\dot{l}\dot{\theta} + m_br_c^2(\ddot{\theta} + \ddot{\phi}) &= -(m + m_b)gl\cos\theta - m_bg r_c (\cos(\theta + \phi)) \\m_br_c^2(\ddot{\theta} + \ddot{\phi}) &= -m_bg r_c (\cos(\theta + \phi))\end{aligned}$$

4 Simulations

4.1 1 DOF Vertical Hopper with Open-loop Control[11]

System Setup

- Body mass $m = 1$ kg with massless leg, $l = 1$ m.
- Spring parameters: $\omega_n = 30$ rad/s, $\xi = 0.15$ (or equivalently, $kp = 900, kd = 9$)
- Static initial condition, COM height = 1.3 m (foot to ground = 0.3 m)
- Open-loop external force:

$$f_n(t) = \begin{cases} f_n \in \mathbb{C}, & \text{if } t \in t_{on}. \\ 0, & \text{otherwise.} \end{cases}$$

- t_{on} : The duration of actuator activation, starts when the spring reaches the maximum compression, ends when the contact point leave the ground.

Figure 3: Ground reaction force when $f_n = 10$ N

Figure 4: The vertical hopper, the blue dot at the bottom is the contact point of the massless leg.

Figure 5: Phase portrait (stable spiral) of $f = 1$ N, period 0 sec

Figure 6: Phase portrait (stable limit cycle) of $f = 10$ N, period 0.27sec, (closer to the damped natural period $\cong 0.3295$ sec)

Figure 7: Phase portrait (stable limit cycle) of $f = 50$ N, period 0.859 sec

Figure 8: Phase portrait of $f = 100$ N, no stable limit cycle evolved (might be bifurcation).

Plan

- Go through and reuse the Poincare analysis in spokedReader package.

- Could be a good case for me to learn how to use parameterOptimizer (or other constrained nonlinear program solver) to get IC/parameters for a stable/optimal gait.

4.2 Abstract Runner with Open-loop Normal Force and Closed-loop Pitch Angle Control

System Setup

- Body mass $m = 10$, $I_{yy} = 10$ with massless leg, $l = 1$.
- Reuse the vertical hopper above, change the initial condition to $\theta = 0.2$
- No force applied in the x direction, \dot{x}_0 can be 0 (hopper) or a constant (runner).
- Similar to the abstract runner (Fig. 9), enforces the on/off timing of ground reaction force $f_n(t)$:

$$f_n(t) = \begin{cases} (f_n + u) | f_n \in \mathbb{C}, & \text{if } t \in t_{on}. \\ 0, & \text{otherwise.} \end{cases}$$

where $f_n = \alpha * mg$, $\alpha \in \mathbb{C}$, u is the force from PD control, $kp_z = 80, kd_z = 6$. $kp_{pitch} = 80, kd_{pitch} = 6$

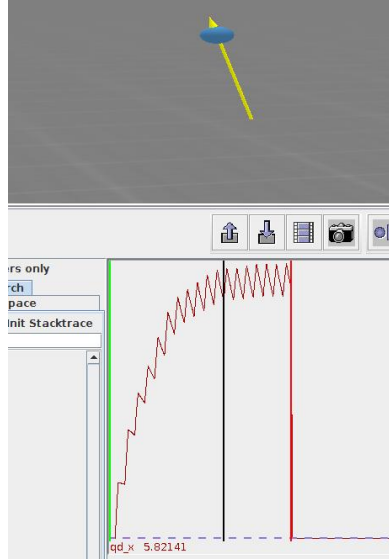

Figure 9: The Abstract Runner

Figure 10: The phase portrait of the abstract runner: phase portrait (left) of body z movement $[q_z, qd_z]^T$ and the pitch motion (right, the movement is converging to the origin in the upper-left corner) .

Plan

- Link it to the Math from Jerry's note (analysis of a linear Poincare map) to get the boundaries of stable parameters.

4.3 Spoked Runner with Massless Legs

System Setup

- $m = 15$, $I_{yy} = 10$, $l = 4$, $r_{penetration} = 0.3$ (the distance the virtual wheel penetrate into the ground)
- Adjustable spoke leg number
- Fixed rotation rate w.r.t inertial frame
- Setup of contact force: PD control
 - w.r.t to world frame
 - w.r.t to inertial frame (virtual pivot point)
- Assuming no friction (Could be an bad idea?)

Figure 11: The Spoked Runner with three legs

Plan

- Smoothly change the leg length, or the rotational speed of the virtual wheel, and observe the system response.
- Learn how to use GUI for parameter adjustment with SCS.

5 Code implementation

5.1 Modeling and Parameters

Main idea: a virtual wheel (as the massless leg) with radius r_{wheel} penetrate the ground for a distance r_{pen} where a external force point pe is attached on it. A body (with mass m and inertia I_{yy}) is attached to the center of wheel. Using PD control to interpret contact force when p_e is under the ground.

06/07 First prototype (Not used now)

- Joint numbers: 2
- Joint types: Floating planer joint for virtual wheel and pin joint for the body link.
- Contact point type: External force point
- Virtual wheel rotation: set proper initial condition for virtual wheel (also need a large inertia to make it nearly constant).

Contact force: Assuming the ground height is 0,

$$F_z = kp(0 - pe_z) + kd(0 - ve_z) \quad (1)$$

$$\phi = atan2(pe_x, r_{wheel} - pe_z) \quad (2)$$

$$F_x = F_z tan(\phi) \quad (3)$$

where ve is the velocity vector of the contact point pe , kp and kd are the PD control parameters. F_x is calculated so that the vector of ground reaction force $[F_x, F_y, F_z]^T$ will point towards the virtual pivot (the center of the virtual wheel).

Assessments:

- Need to set a non-zero inertia of massless virtual wheel (for numerical stability), otherwise the simulation will diverge.
- The inertia of virtual wheel need to be a large one for constant rotational speed.
- Suggestions: remove the massless link, attach the external force point to the body and change its position in the controller every time step.

06/08 Round Runner

- Joint numbers: 1
- Joint types: Floating planer joint for the body link.
- Contact point type: External force point
- Virtual wheel rotation: Assigning the external force point location with respect to the joint in an open loop manner.
- Contact force: Assuming the ground height is 0,

$$F_z = kp(0 - pe_z) + kd(0 - ve_z) \quad (4)$$

$$\phi = atan2(pe_x, r_{wheel} - pe_z) \quad (5)$$

$$F_x = F_z tan(\phi) \quad (6)$$

where ve is the velocity vector of the contact point pe , kp and kd are the PD control parameters. F_x is calculated so that the vector of ground reaction force $[F_x, F_y, F_z]^T$ will point towards the virtual pivot (the center of the virtual wheel).

Assessments:

- The ground reaction force looks better, while the energy is not balanced (after a while it will move towards the negative x direction)
- The inertia of virtual wheel need to be a large one for constant rotational speed.
- Suggestions: Use the ground contact point (instead of external force point) to see how it goes.

06/11 Round Runner(with Ground Contact Point)

- Joint numbers: 1
- Joint types: Floating planer joint for the body link.
- Contact point type: Ground contact point, linear contact model¹
- Virtual wheel rotation: Assigning the external force point location with respect to the joint in an open loop manner.
- **Contact point number** Parameterized, currently set to 3-6 points.
- Contact force: using built-in functionalities, only assigning the kp , kd (PD parameters in the z direction), kp_x , and kd_x (PD parameters in the x/y directions).

Assessments:

- Was able to generate a stable walking. Contact point has sliding.
- Due to setting up stiffness and damping for x and z separately, the force is not always point towards the virtual pivot.

06/12 Round Runner(with External Contact Point Point)

- Implement the same one as 06/11, but replace the ground contact point to the external one (because it is more complex for ground contact point to adjust stiffness/damping as parameters.)
- implement the linear ground contact model basically.

06/13 Round Runner

- Parameterize contact point numbers
- Adding enum for switching between different setup: contact point type and the corresponding ground reaction force calculation: (w.r.t to the world frame or inertia frame.)

06/16 Round Runner (vertical hopper)

- Adding vertical hopper with open-loop force control
- Playing with open-loop force magnitudes for different stability conditions

¹Disable the hardening stiffness in z direction by setting `groundStiffeningLength` to `Double.NEGATIVE_INFINITY`

6 Info might be useful

6.1 Finding a fixed-point solution from numerical Poincare map

If the analytical solution of Poincare map can be derived, then one can obtain the fixed-point easily. The followings are related methods (best to my knowledge) to get fixed-points of Poincare map through simulations:

Finding stable fixed-points

Take a collection of state at Poincare section defined (e.g. at touch down, or the end of the support phase, etc.) as $[x_1, x_2, \dots, x_n]'$. Take the first $n - 1$ states as $X_n = [x_1, x_2, \dots, x_{n-1}]'$ and the last $n - 1$ states as $X_{n+1} = [x_2, x_3, \dots, x_n]'$, the map A can be approximated as:

$$\begin{aligned} X_{n+1} &= A(X_n) \\ \rightarrow A &= X_{n+1}/(X_n) \end{aligned}$$

If the system has a stable fixed point x^* , then the following should be satisfied:

$$\lim_{n \rightarrow \infty} x^* = x_n = Ax_{n-1} = A^n x_1 = x_{n-1}$$

Note:

- If A is invertible, the unstable fixed point might be derived by calculating the Poincare section in the backward manner.
- Whether the fixed-point is accurate enough is also depending on the quality of data (whether the data is sufficiently rich).
- Unlike the method like PCA, the data can only be subtracted by the fixed-point, otherwise the dynamics will be changed (scaling like dimensionless analysis is okay).

Finding fixed-points

The more general way to find fixed-point is to simulate the system, and evaluate the difference of the periodic condition at the Poincare section as the cost/constraint. Trajectory Optimization

- Single Shooting
- Multiple Shooting
- Direct Collocation

6.2 Going through references

1. Compare different terrestrial locomotions: Some parameters of the walk are not speed- dependent. The swing duration is a constant time parameter [1].
2. Trunk plays an important role during walking (birds) [2].
3. The use of these drives (Resonance drives, with adaptive control) allows increasing machine's quickness several times and decreasing energy expenses simultaneously 10-50 times [3].
4. Light weight leg (ostrich vs. moa) can run faster[5]. Also a famous allometric equation:

$$Y = M^{3/4} \tag{1}$$

where M is the body mass, Y is the metabolic rate.

5. Human's walking may not be really self-optimized: the preferred speed maybe different from the energetically optimal speed[8].

6. It is concluded that the most important adjustment to the bodys spring system to accommodate higher stride frequencies is that leg spring becomes stiffer [19].
7. magic equations for imd force (ostrich) [26]
8. gait frequency was reported to be highly correlated with the resonant frequency of the mass-spring model [30]
9. WABIAN, why you are here? [31]
